Course : Software Engineering

Topic : Report week 2 Library Management tracking System

Name Student	ID of student	Score
RIN NAIRITH	e20221557
THOU LAIHENG	e20220843

Lecturer: **Mr. ROUEN Pacharoth**

Academic year 2025-2026

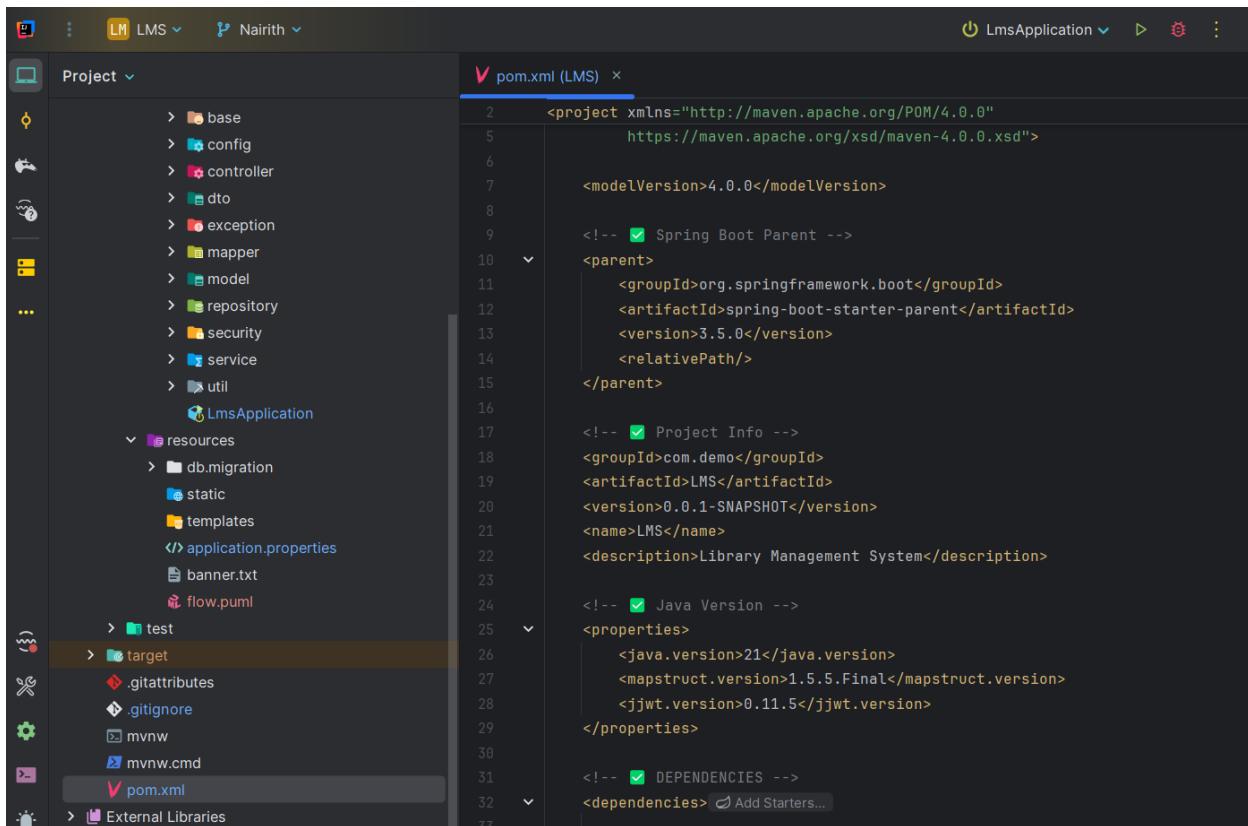

1. Project Setup and Environment Configuration

During Week 1, the initial setup of the **Library Management System (LMS)** backend was completed using **Spring Boot**. The project was created as a **Maven-based Spring Boot application**, ensuring modularity and ease of dependency management.

The following technologies and tools were configured:

- **Spring Boot 3.x** for application development
- **Java (JDK 21/25)** as the programming language
- **MySQL** as the relational database
- **Spring Data JPA (Hibernate)** for ORM and persistence
- **Flyway** for database version control and migration
- **Spring Security** for password encryption and future authentication
- **Swagger (OpenAPI)** for API documentation

The project follows a **layered and feature-based architecture**, separating concerns into controller, service, repository, DTO, mapper, entity, and configuration layers. This structure improves maintainability and scalability.

The screenshot shows the IntelliJ IDEA interface with the following details:

- Project View:** Shows the project structure under the **LmsApplication** module. It includes packages like base, config, controller, dto, exception, mapper, model, repository, security, service, util, and resources (db.migration, static, templates, application.properties, banner.txt, flow.puml). A **target** folder is selected.
- pom.xml (LMS) Editor:** Displays the Maven configuration file. Key sections include:
 - <parent>**: Points to org.springframework.boot as the parent with artifactId spring-boot-starter-parent, version 3.5.0, and relativePath .
 - <properties>**: Sets java.version to 21, mapstruct.version to 1.5.5.Final, and jjwt.version to 0.11.5.
 - <dependencies>**: A placeholder for adding starters.

```
<!--  Java Version -->
<properties>
    <java.version>21</java.version>
    <mapstruct.version>1.5.5.Final</mapstruct.version>
    <jjwt.version>0.11.5</jjwt.version>
</properties>
```

2. Database Design and Table Definition

A conceptual database design was created to support a Library Management System.

For Week 2, the focus was placed on **user and role management**, which is a core foundation for authentication and authorization.

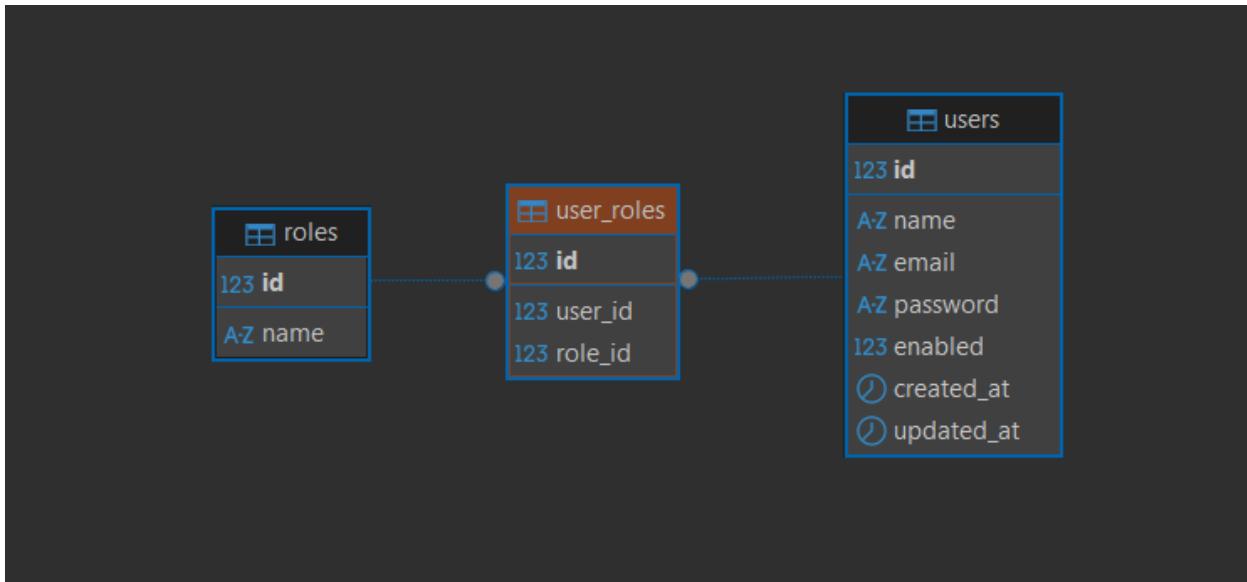

The following tables were defined and implemented:

- **Users** : Stores system user information such as name, email, and password.
- **Roles** : Stores predefined roles used for authorization.
- **user_roles** : A junction table implementing a many-to-many relationship between users and roles.

Relationships:

- One user can have multiple roles.
- One role can be assigned to multiple users.

Database constraints such as **primary keys**, **foreign keys**, **unique email constraint**, and **non-null role assignment** were applied to maintain data integrity.

3. CRUD Operations for User Management

Completed **CRUD (Create, Read, Update, Delete)** functionality was implemented for user management following RESTful API principles.

Implemented Operations:

- **Create User**
 - Validates input data using DTO validation.
 - Encrypts passwords using BCrypt.
 - Automatically assigns a default role (STUDENT).
- **Read Users**
 - Retrieve all users with their assigned roles.
 - Retrieve a single user by ID.
- **Update User**
 - Update name, email, and password.
 - Password is re-encrypted if changed.
- **Delete User (optional extension)**
 - Remove a user safely from the system.

The service layer handles business logic, repositories manage database access, and mappers convert entities into response DTOs. Transactions were managed correctly to prevent lazy-loading and data consistency issues.

The screenshot shows a Swagger UI interface for a 'User Management' API. The title bar says 'User Management APIs for managing users in the library system'. Below it is a list of seven API endpoints, each with a method (DELETE, GET, PATCH, POST, PUT), path, and description. Each endpoint has a lock icon and a dropdown arrow to its right.

User Management APIs for managing users in the library system	
DELETE	/api/users/{id} Delete user
GET	/api/users/{id} Get user by ID
GET	/api/users Get all users
PATCH	/api/users/{id}/status Update user status
POST	/api/users Create a new user
PUT	/api/users/{id} Update user

4. Database Migration and Role Initialization

Flyway migrations were used to version-control the database schema.

Implemented Migrations:

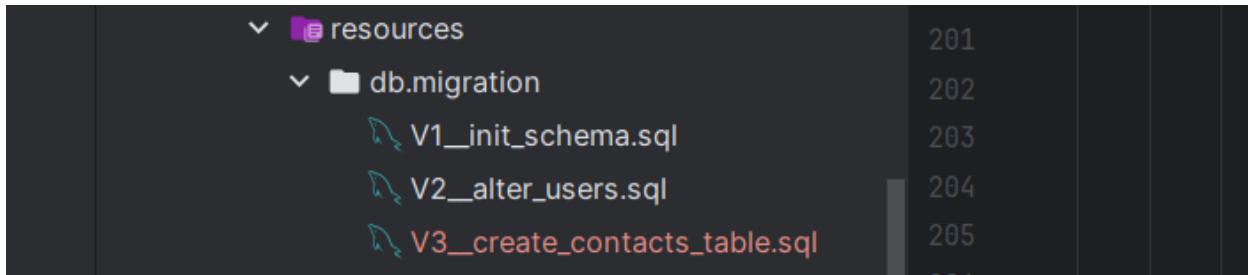

- **V1** – Initial schema creation (users, roles, user_roles)
- **V2** – Role initialization and adjustment

In **V2**, default roles were inserted:

- **ADMIN**

- LIBRARIAN
- STUDENT

This ensures that all environments (development, testing, production) have consistent role data without manual database setup. Role values were synchronized with Java enums using `EnumType.STRING` for safety and clarity.

The screenshot shows a database management interface with tabs for 'roles', '*user_roles', and 'users'. The 'users' tab is active, displaying a grid of user data. The columns are: id, name, email, password, enabled, created_at, and updated_at. There are three rows of data:

	id	name	email	password	enabled	created_at	updated_at
Grid	1	System Administrator	admin@lms.com	\$2a\$10\$DOWTQX/jQ7zqpq7p5VUW3eoBnp	1	2025-12-17 11:25:06	2025-12-17 11:25:06
Text	2	Head Librarian	librarian@lms.com	\$2a\$10\$FOwTQX/jQ7zqpq7p5VUW3eoBnp	1	2025-12-17 11:25:06	2025-12-17 11:25:06
Text	3	Demo Student	student@lms.com	\$2a\$10\$HOwTQX/jQ7zqpq7p5VUW3eoBnp	1	2025-12-17 11:25:06	2025-12-17 11:25:06

5. Swagger API Documentation Integration

Swagger (OpenAPI) was integrated to provide **interactive API documentation**.

Features:

- Automatic documentation of all REST endpoints
- Ability to test APIs directly from the browser
- Clear visualization of request/response models

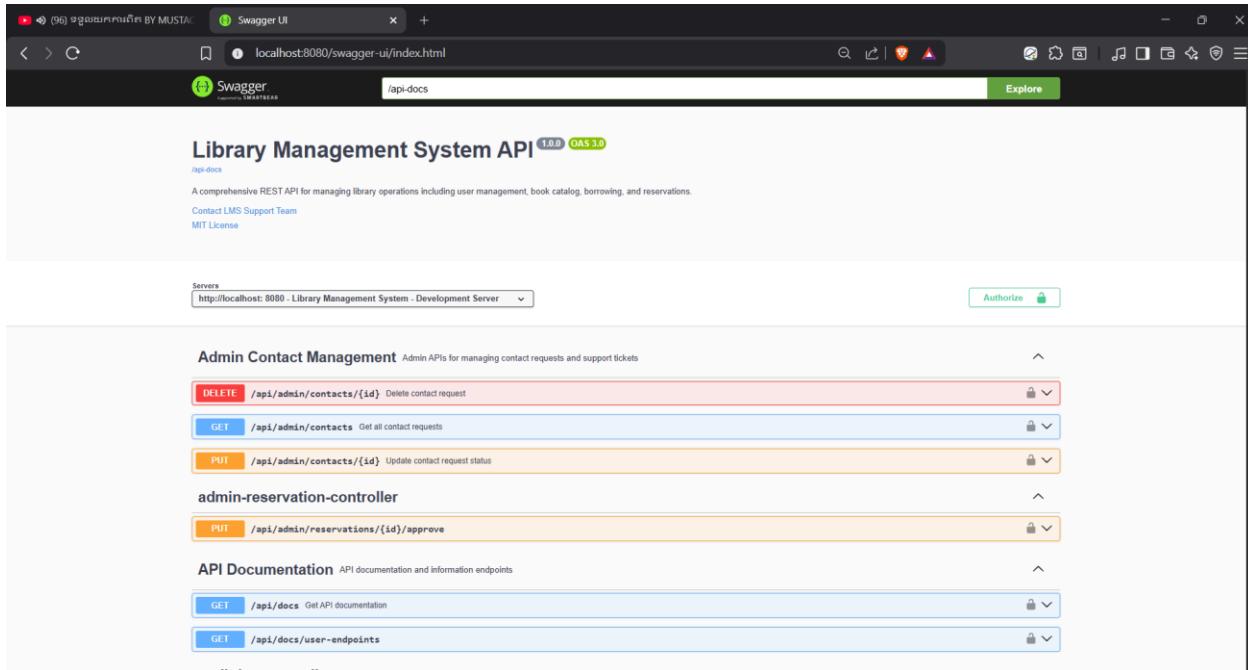

Swagger was configured to work alongside Spring Security in development mode, allowing unrestricted access to API documentation.

Access URL:

<http://localhost:8080/swagger-ui.html>

<http://localhost:8080/api/-docs>

This improves collaboration, testing efficiency, and project presentation quality.

Laiheng Part :

6. Add Dependencies:

- Add dependency spring security:
For apply the protection in your web application like authentication, authorization, sessions, password, hashing, CORS, CSRF, JWT and more.
- Add dependency jwt(JSON web token): (secure and authentication (Suitable for REST API protection)):
 - jjwt-impl it is used jjwt-api like algorithm, parser, claim handling logic so that is why we need for runtime
 - jjwt-jackson use for serialize or deserialize
 - jjwt-api the one which use as public API

7. Configure the SecurityConfig:

- Add password method by using bcrypt

- `@Configuration` use for load the methods inside which has `@Bean` so all method that use annotation `@Bean` will be recognize in Spring Boot (Singleton register)
- `@EnableMethodSecurity` configure in `SecurityConfig` for enabling the annotation `@PreAuthorize`, `@PostAuthorize`, `@Secure`, `@RolesAllowed` (those annotation refer to the authentication and authorization to use specific method in our controller)

```
@Configuration
@EnableWebSecurity
public class SecurityConfig {
    private final JwtFilter jwtFilter;

    public SecurityConfig(JwtFilter jwtFilter) {
        this.jwtFilter = jwtFilter;
    }
}
```

```
@Bean
public PasswordEncoder passwordEncoder() {
    SecureRandom secureRandom;
    try{
        secureRandom = SecureRandom.getInstanceStrong();
    } catch (Exception e) {
        secureRandom = new SecureRandom();
    }
    return new BCryptPasswordEncoder(12, secureRandom);
}
```

8. Testing password:

- Testing does the spring recognize the password method that we plugin in our `SpringSecurity` or not?
- Create `AuthController` and use a route for `/api/login` as testing password json by passing the request body with password
- But we need to configure the filter security as well when you want to make sure your route authorize.

```
@PostMapping("/api/login")
public ResponseEntity<?> loginAPI(@RequestBody LoginRequest loginRequest)
{
    String email = loginRequest.getEmail() == null ? null :
    loginRequest.getEmail().trim().toLowerCase();
```

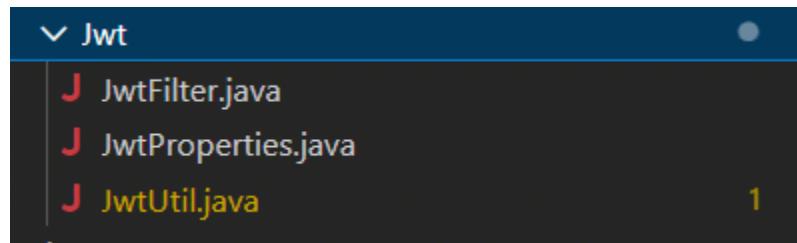

```

        return userRepository.findByEmail(email)
            .filter(u -> encoder.matches(loginRequest.getPassword(), u.password))
            .<ResponseEntity<?>>map(u -> ResponseEntity.ok(new
AuthResponse(u.email, jwtUtil.generateToken(u.email))))
            .orElseGet(() -> ResponseEntity.status(HttpStatus.UNAUTHORIZED)
                .body(Map.of("error", "Invalid credentials")));
    }
}

```

9. Create JwtUtils

- To generate token and extract username from the token and using @Component to make your spring boot recognize that util class.
- Generate SecretKey from secretkey of JwtProperties and then load the properties and create the expiry date for generate token.
- To verify the token, we need the key existing and parse with the token that user apply, and then extract the email

```

@Component
public class JwtUtil {
    private JwtProperties jwtProperties;
    private SecretKey key;

    public JwtUtil(JwtProperties jwtProperties) {
        this.jwtProperties = jwtProperties;
        this.key =
Keys.hmacShaKeyFor(Base64.getDecoder().decode(jwtProperties.getSecretKey()));
    }

    public String generateToken(String email){
        Date now = new Date();
        Date expiryDate = new Date(now.getTime() +
jwtProperties.getExpirationTime());
        return Jwts.builder()
            .subject(email)
            .issuedAt(now)
            .expiration(expiryDate)
    }
}

```

```

        .signWith(key)
        .compact();
    }

    public String extractEmail(String token){
        return extractAllClaims(token).getSubject();
    }

    private Claims extractAllClaims(String token){
        return Jwts.parser()
            .verifyWith(key)
            .build()
            .parseSignedClaims(token)
            .getPayload();
    }
}

```

10. Modify the SecurityConfig

- Add authProvider into authenticationProvider method in httpSecurity that we created.
- Mapped the login page into that request
- Enable cors
- PermitAll route related to login, /api/login, /register
- /products protected authenticated
- Pass the filter jwt that we create to filter header if they use API

```

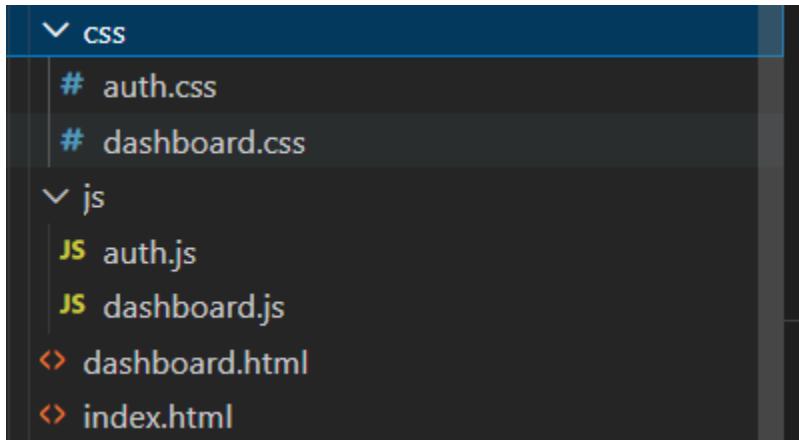

@Bean
    public SecurityFilterChain securityFilterChain(HttpSecurity http) throws
Exception {
    http
        .csrf(csrf -> csrf.disable()) // Disable CSRF for API development
        .authorizeHttpRequests(auth -> auth
            // Static resources & root - public access
            .requestMatchers(PathRequest.toStaticResources().atCommonLocation
s()).permitAll()
            // Swagger/OpenAPI endpoints - public access
            .requestMatchers("/api/login", "/login",
                "/register","/api/register").permitAll()
            // Actuator endpoints - public access
            .anyRequest().authenticated()
        )
        .addFilterBefore(jwtFilter,

```

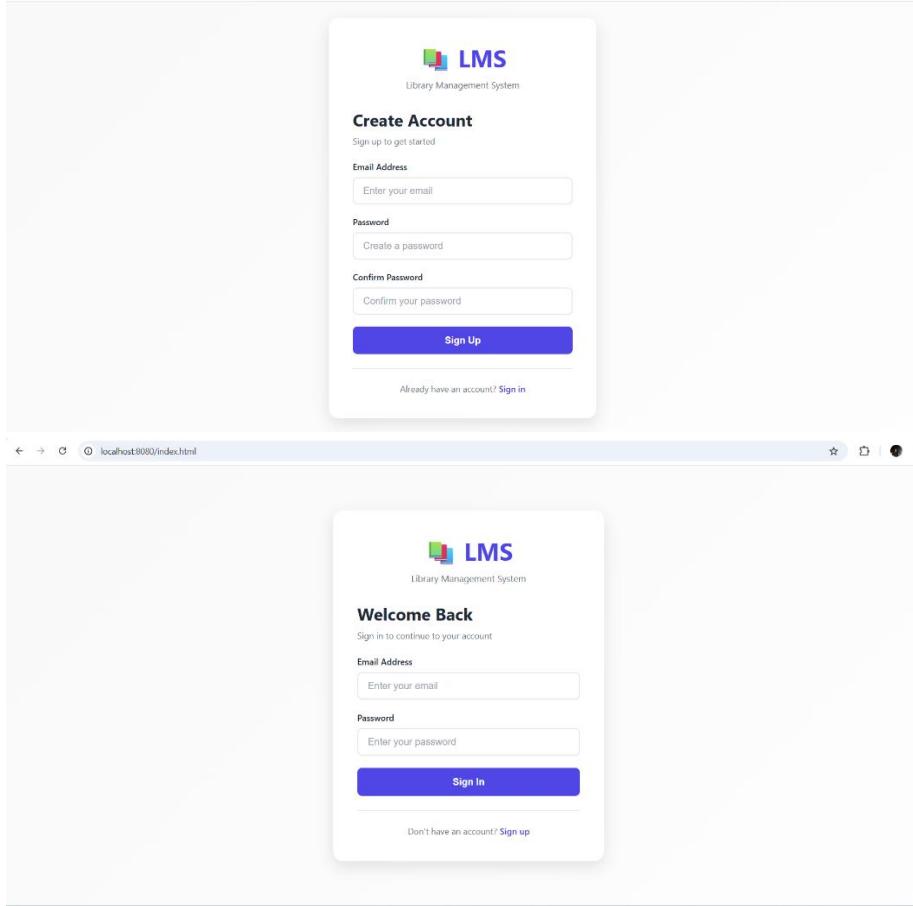

```
org.springframework.security.web.authentication.UsernamePasswordAuthenticationFilter.class);

    return http.build();
}
```

11. Create the UI for SignUp and LogIn

User Interface:

12. Conclusion

By the end of Week 2, the project achieved the following milestones:

- Successfully set up a Spring Boot backend project
- Designed and implemented core database tables with relationships
- Implemented full CRUD operations for user management
- Initialized roles using Flyway database migration
- Integrated Swagger for API documentation and testing
- Configure the SecurityConfig
- Create JwtUtils
- Modify the SecurityConfig
- Create UI for SignUp and Login

This week established a **strong and scalable foundation** for future features such as authentication (JWT), book management, borrowing workflows, and authorization control.

Planned Work for Week 3

- Integrating access control logic on the frontend to display elements relevant to the authenticated user's role
- Managing user session state
- Implementing the borrowing/returning logic and the overdue detection mechanism (calculating due dates and flagging late returns).
- Integrating access control logic on the frontend to display elements relevant to the authenticated user's role
- Handling book search, filtering, and inventory updates.
